

1. What are Modules in Metasploit?

In Metasploit, a **module** is like a **tool or small program** that performs a specific task in hacking or penetration testing.

You can think of Metasploit like a **toolbox**, and modules are the different tools inside it — like screwdrivers, pliers, wrenches — each used for a different job.

Types of Metasploit Modules (Explained Simply)

A. Exploit Modules- 2529

- These are **attack tools**.
- They **target a known vulnerability** in the system or software (like breaking a lock that has a known weakness).

♦ Example:

If a computer is running an old version of a web server with a known bug, an exploit module can be used to break in.

👉 Think of this like a master key that opens a weak lock.

B. Payload Modules

- These are **what gets delivered** *after* the exploit is successful.
- It's the code that **runs on the target system**, like opening a backdoor.

♦ Types of Payloads:

- **Reverse Shell**: Target system connects back to attacker's system.
- **Meterpreter**: Advanced payload for control, screenshots, keystrokes, etc.

👉 Imagine you broke into a house (using exploit), now payload is the camera you install inside to monitor.

C. Auxiliary Modules

- These are **helper tools**. They **do not exploit**, but help gather information or perform attacks like scanning.

♦ Examples:

- Port scanning (like Nmap)
- Banner grabbing (find out software versions)
- Password brute-force
- DoS attack tools

👉 Like surveillance before robbery — watching the target before making a move.

D. Post-Exploitation Modules

- These are used **after** you've broken into the system.
- Help you **gather data**, **move deeper**, or **stay hidden**.

♦ Examples:

- Dump saved passwords
- Capture webcam
- List installed applications

- Create hidden user

👉 Like stealing valuables **after** breaking into a house.

E. Encoders

- Used to **hide** or **scramble** the payload so antivirus doesn't detect it.
- It **changes how the code looks** without changing what it does.

♦ Example:

A reverse shell is encoded so it looks harmless.

👉 Like changing clothes to avoid being identified on security cameras.

F. NOP Generators (No Operation)

- Adds "**do nothing**" instructions to the payload.
- Helps in aligning memory addresses or **bypassing basic defenses**.
- ♦ NOP = No Operation. The CPU reads it but does nothing.

👉 Like adding silence between songs so they don't overlap — helps in **timing and smoothness**.

Summary Table

Module Type	Purpose	Real-life Analogy
Exploit	Break into the system	Master key
Payload	Code that runs after break-in	Hidden camera
Auxiliary	Info gathering, scanning	Surveillance
Post	Actions after access (data theft)	Robbing after entry
Encoder	Hide payload from antivirus	Disguise
NOP Generator	Adjust timing/avoid detection	Adding silence
